```

On remarque que toutes less variables ont des valeurs manquantes (3 pour length, 1 pour breadth et height et 2 pour face_height et face_breadth)

Statistiques bivariées

```
Length :
    Le test t de Welch sur la longueur (length) montre une différence significative entre les groupes A

Breadth :
    Le test t de Welch sur la largeur (breadth) ne montre pas de différence significative entre les grou

Height :
    Le test t de Welch sur la hauteur (height) ne montre pas de différence significative entre les group

Face Height :
    Le test t de Welch sur la hauteur du visage (face_height) montre une différence significative entre

Face Breadth :
    Le test t de Welch sur la largeur du visage (face_breadth) montre une différence significative entre
```

```

- breadth : -0.2267. Chaque augmentation d'une unité de la variable 'breadth' est associée à une

diminution de l'odds ratio de 0.2267, bien que cela ne soit pas statistiquement significatif à un niveau de confiance de 95% (p-value = 0.0663).

- height : 0.1048. Chaque augmentation d'une unité de la variable 'height' est associée à une augmentation de l'odds ratio de 0.1048, mais cela n'est pas statistiquement significatif (p-value = 0.3031).
- face_breadth : 0.2387. Chaque augmentation d'une unité de la variable 'face_breadth' est associée à une augmentation de l'odds ratio de 0.2387, bien que cela ne soit pas statistiquement significatif (p-value = 0.1181).
- face_height : 0.4888. Chaque augmentation d'une unité de la variable 'face_height' est associée à une augmentation de l'odds ratio de 0.4888, et cela est statistiquement significatif à un niveau de confiance de 95% (p-value = 0.0439). Cela suggère que 'face_height' a une influence significative sur la probabilité de 'type'

Courbe ROC

```
predictions <- predict(logit_model, d1, type = "response")
roc_obj <- roc(d1$type, predictions)
```

```
## Setting levels: control = A, case = B
```

```
## Setting direction: controls < cases
```

```
plot(roc_obj, main = "Courbe ROC du Modèle Logistique", col = "blue", lwd = 2)
abline(a = 0, b = 1, col = "red", lty = 2, lwd = 2)  # Ligne de référence
```

Calcul du taux de mal-classés avec un seuil de décision de 0.5

```r
threshold <- 0.5
predicted_class <- ifelse(predictions >= threshold, "B", "A")
misclassification_rate <- mean(predicted_class != d1$type)
cat("Taux de mal-classés (seuil de décision = 0.5):", misclassification_rate, "\n")
```

```
## Taux de mal-classés (seuil de décision = 0.5): 0.15625
```
